

Diablo IV Build Overlays & Tools

<https://gemini.google.com/app/2912397b8a792300>

User prompt: is there a plugin or overlay for diablo iv? that shows u build pathing items etc..

Response: Yes, several community tools and overlays display build pathing, skill allocations, Paragon boards, and item stat priorities directly over your game. Because Diablo IV lacks an official addon API like *World of Warcraft*, safe third-party tools run as transparent overlay windows or use OCR (optical character recognition) to read tooltips without modifying game files or injecting into memory.

Top Diablo IV Build & Item Overlays

1. Diablo 4 Companion (Open-Source / GitHub)

- **Best for:** Gear evaluation, affix filtering, and Paragon board pathing.
- **How it works:** It uses an OCR screen-reader to analyze item tooltips when you hover over gear in your inventory. It marks items that match your build's desired affixes, Greater Affixes, and Legendary Aspects.
- **Build Integration:** Allows you to directly import build links from **Maxroll**, **Mobalytics**, and **D4Builds**. It also provides an overlay window showing your exact Paragon board layout, glyph placement, and board rotation order so you do not path incorrectly.

2. Mobalytics Desktop App

- **Best for:** All-in-one in-game build cheat sheet.
- **How it works:** Runs an interactive HUD panel toggled via hotkey.
- **Key Features:** Shows level-by-level skill progression, required Legendary Aspects per gear slot, stat priority rankings for each item, and required Uniques right alongside your game window.

3. D4Builds Desktop Companion

- **Best for:** Lightweight build references and event tracking.
- **How it works:** A companion app tailored to D4Builds.gg. Features quick build guides alongside real-time Helltide and World Boss spawn timers.

4. TH.GL / Overwolf Interactive Map Overlay

- **Best for:** Overworld routing and collectible pathing.
- **Key Features:** Offers an overlay for tracking Altars of Lilith, Tenets of Akarat, Whispers, and dungeon locations with optional live player tracking.

Safety and Anti-Cheat Rules

Blizzard's Terms of Service strictly prohibit **memory injection, automated gameplay (botting), and reading internal client memory**.

- **Safe:** Tools like **Mobalytics** and **Diablo 4 Companion** operate via non-invasive transparent windows or screen-pixel capture (OCR), which do not hook into `DiabloIV.exe`.
- **Avoid:** Any tool derived from memory-reading injectors (such as old TurboHUD forks or .dll injectors), which trigger Blizzard's Warden anti-cheat system and can lead to permanent account bans.

User prompt: *mobalytics has ads?*

Response: **Yes, the free version of Mobalytics includes ads.**

Where Ads Appear

- **Desktop Client:** Display banners and autoplay video ads appear across the navigation menus, build guides, and side panels.
- **In-Game Overlay:** Small static or video banner ads display in the border areas of the overlay panel. They do not obscure core build data, but they do take up screen space.

Common Issues with the Free Tier

- **Performance Impact:** Mobalytics runs on an Electron framework (or Overwolf, depending on the version you install). Rendering dynamic/video ads alongside the app can lead to background CPU/RAM spikes, which can trigger micro-stutters in demanding games like *Diablo IV*.
- **Bandwidth:** Video ad preloading can consume minor background network bandwidth.

How to Avoid Ads

- **Mobalytics Plus:** A paid subscription (~\$6 to \$10/month, depending on the billing cycle) completely removes all ads across the app and overlay.
- **Use Diablo 4 Companion Instead:** If you want an overlay strictly for builds, Paragon pathing, and gear affix filtering without advertisements or subscriptions, **Diablo 4 Companion** is 100% free and open-source on GitHub. Because it operates strictly via local screen-reading (OCR) without third-party ad networks, it carries almost zero system overhead.

User prompt: *is there a league of legends ad free overlay or whatever which shows u live info about the players in ur game their match history win rate most played a bit or more like exactly like porofessor u know the one u can toggle with ctrl + X*

Response: **There is no 100% free, ad-free standalone overlay that replicates Porofessor's live player scouting.**

Unlike tools for *Diablo IV* that simply read your local screen pixels (OCR), a live League scouting overlay must query Riot's production API for 10 players simultaneously, pull hundreds of past matches, calculate custom behavioral tags ("Cold streak", "OTP", "Aggressive laner"), and serve it in real time.

Because hosting that database and compute pipeline costs thousands of dollars monthly in server infrastructure, every major live scouting app—**Porofessor**, **Blitz**, **OP.GG**, and **Mobalytics**—monetizes through ads or subscriptions. Newer open-source/ad-free League tools (like *Warden* or *Hexgate*) explicitly skip player scouting for this exact reason and stick only to local rune imports or itemization.

However, you have three practical workarounds to get the Porofessor experience without dealing with video ads:

1. Strip the Ads from Porofessor / Overwolf via DNS

If you love Porofessor's exact interface, live tags, and the Ctrl + X toggle, the most common solution is to keep the app and block Overwolf's ad delivery endpoints at the network/system level.

- **Use NextDNS or Pi-hole:** Add standard ad-blocking filters (like *OISD* or *AdGuard DNS filter*) to your DNS resolver.
- **What happens:** Porofessor will still query match and player data normally via its backend API, but Overwolf's embedded video player will fail to fetch ad inventory. The ad slot collapses or remains an empty gray box, eliminating the audio/video popups that cause in-game frame drops.

2. OP.GG Desktop (Standalone Overlay)

If you want to ditch Overwolf entirely, **OP.GG Desktop** runs as a native standalone client.

- **In-Game Overlay:** Uses an in-game toggle (customizable, default Ctrl + Tab or Shift + Tab) to bring up live 10-player match cards.
- **Scouting Info:** Displays current rank, seasonal win rate, win rate on their current champion, recent match performance streaks, and primary runes.
- **Ad Situation:** While the free client window has banner space, the in-game overlay itself is drastically cleaner and less intrusive than Porofessor/Overwolf's video ad units.

3. Browser Live Scouting + uBlock Origin (Second Screen / Alt-Tab)

If you play with a second monitor or don't mind a quick Alt + Tab during the loading screen:

- Open **Porofessor.gg**, **DeepLoL**, or **OP.GG Multi-Search** in a browser running **uBlock Origin**.
- Because player names are hidden in Ranked champion select until the loading screen begins, you can simply search your own Summoner Name on Porofessor.gg once the game loads.
- You get the exact same live match breakdown, playstyle tags, and match histories without running any background Electron apps, Overwolf bloat, or third-party hooks alongside Riot Vanguard.

User prompt: what if i just build it myself with antigravity? clean lightweight overlay whichi can toggle with ctrl + X and shows me live data from the players in my game with useful information

Response: Building your own tool is not only feasible, but **you have a massive advantage over commercial apps**: because it only runs for your own matches, you don't need expensive server clusters or database hosting. A free Riot Developer API key easily handles querying 10 players every 30 minutes.

With Antigravity orchestrating the project, you can scaffold and build this in an afternoon.

The Architecture: How It Works

To keep it lightweight, responsive, and 100% safe from Vanguard bans, your tool should consist of three decoupled components:

1. Live Match Detection (Local In-Game API)

You do not need to scrape screens or inject into game memory. When a League game starts, the game engine hosts a local HTTPS server:

- **Endpoint:** [https://127.0.0.1:2999/liveclientdata/allgamedata] (https://127.0.0.1:2999/liveclientdata/allgamedata) (or /playerlist).
- **What it gives you:** The Riot IDs (gameName#tagLine), champion names, and team sides for all 10 players in the match.
- **Vanguard safety:** 100% compliant. This is Riot's official local API for spectator displays and hardware integrations (like Razer Chroma).

2. Stats Aggregation (Riot Web API)

Once your local script detects the 10 players from port 2999:

1. Query **ACCOUNT-V1** with the Riot ID to get each player's puuid.
 2. Query **LEAGUE-V4** to get their current Solo/Duo rank, LP, wins, and losses.
 3. Query **MATCH-V5** (last 5–10 matches) to compute:
 - Current champion win rate / games played.
 - Recent form (e.g., win streaks or losing skews).
 - Primary roles and KDA averages.
- **Rate Limits:** Riot's free development key permits **20 requests/second** and **100 requests every 2 minutes**. Fetching data for 10 players takes ~25 requests once per game, well within the free limit.

3. The Overlay Window & Toggle (Ctrl + X)

- **Technology:** Use **Tauri** (Rust + HTML/CSS) or **Python (PyQt6 / PySide6)** with a frameless, transparent window. Tauri is ideal because its idle memory footprint is typically 15–25 MB (compared to Electron/Overwolf taking 300–600 MB).
- **Game Setting:** League must be set to **Borderless Windowed** (not Exclusive Fullscreen).
- **Window Properties:** Set the window to Always on Top, transparent background, and register a global hotkey hook for Ctrl + X that toggles the window's visibility (hide() / show()).

Implementation Blueprint for Antigravity

You can delegate the implementation to Antigravity by breaking it down into distinct tasks in your workspace:

Phase 1: The Local Game Poller & Riot API Client

Ask Antigravity to write the core data engine first:

"Create a Python backend that polls https://127.0.0.1:2999/LiveClientdata/playerList every 3 seconds (ignoring local self-signed SSL errors). When 10 players are detected, query the official Riot Games API using my RIOT_API_KEY: resolve each player's PUUID, fetch their Solo/Duo rank from LEAGUE-V4, and fetch their last 5 match IDs from MATCH-V5 to calculate champion win rates and recent KDA. Cache results in memory so it only queries once per match."

Phase 2: Global Hotkey & Transparent UI Window

Task Antigravity with building the minimalist UI:

"Build a lightweight transparent desktop overlay using PyQt6 (or Tauri). Requirements:

- *Frameless, always-on-top, dark glassmorphism styling.*
- *Listen for a global Ctrl + X hotkey to toggle window visibility on/off.*
- *Display two columns (Blue Team vs Red Team) showing champion icon, player rank, champion win rate %, and simple tags (e.g., 'Hot Streak', 'OTP', 'Off-role').*
- *Connect it to the backend match data via a local WebSocket or IPC."*

Two Critical Details to Keep in Mind

1. **Riot Developer API Key Expiration:** A default personal development key from developer.riotgames.com expires every **24 hours**.
 - To avoid regenerating it daily, submit a **"Personal Project" application** in the Riot Developer Portal. Approval is typically fast for private personal tools and grants a persistent API key.
2. **Vanguard Compliance:** As long as your overlay is a **separate OS window rendered on top of the borderless game**, Vanguard will not touch it. **Never** use DirectX hooks, DLL injectors, or tools that read League's virtual memory (ReadProcessMemory), as Vanguard's kernel driver will immediately flag them.
